

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

# Female Monthly Sexual Cycle

Dr Zubia Shah

# Learning Objectives

By the end of the lecture a second year MBBS student should be able to

- Describe the monthly ovarian cycle.
- Describe the effects of gonadotropic hormones on the ovaries.
- Describe the monthly Endometrial Cycle and Menstruation.
- Explain the regulation of female monthly Rhythm by hormonal interplay.

# The Monthly Sexual Cycle

**FSH and LH are secreted by anterior Pituitary at 9-12 years of age**

**Puberty and Menarche**

**Average menstrual cycle is 28 days**

**20 to 45 days in some women  
Abnormal length is associated with decreased fertility**

# The Female Monthly Sexual Cycle

**Starts at Puberty and Ends at  
Menopause**

**Each cycle - the female reproductive tract is  
prepared for fertilization and implantation of  
an ovum from the ovary at ovulation**

**If fertilization does not occur, the cycle  
repeats**

**If fertilization occur → Pregnancy  
the cycles are interrupted**

<b>CYCLE</b>	<b>PRE-OVULATION</b>		<b>OVULATION</b>	<b>POST-OVULATION</b>	
<i>Ovarian cycle</i>	<i>FOLLICULAR PHASE</i>			<i>LUTEAL PHASE</i>	
<i>Uterine cycle</i>	<b>PERIOD</b>	<b>PROLIFERATIVE</b>		<b>SECRETORY</b>	

*Cycle*

# THE OVARIAN CYCLE

## FOLLICULAR (preovulatory) PHASE

<b>Step 1</b> <i>Primordial Follicle to Primary Follicle</i>	<b>Step 2</b> <i>Primary Follicle to Secondary Follicle</i>	<b>Step 3</b> <i>Secondary Follicle to Tertiary Follicle</i>
---	--	---

[FSH & ESTROGENS]

## LUTEAL (postovulatory) PHASE

<b>Step 4</b> <i>Tertiary follicle to Ovulation</i>	<b>Step 5</b> <i>Ovulation to Corpus Luteum</i>	<b>Step 6</b> <i>Corpus Luteum to Corpus Albicans</i>
--	--	--

[LH & PROGESTRONE]

# THE UTERINE CYCLE

<b>MENSTRUAL</b> (menses) 1-5	<b>PROLIFERATIVE</b> 6-14	<b>SECRETORY</b> 15-26	<b>PREMENSTRUAL</b> 27-28
-------------------------------------	------------------------------	---------------------------	------------------------------

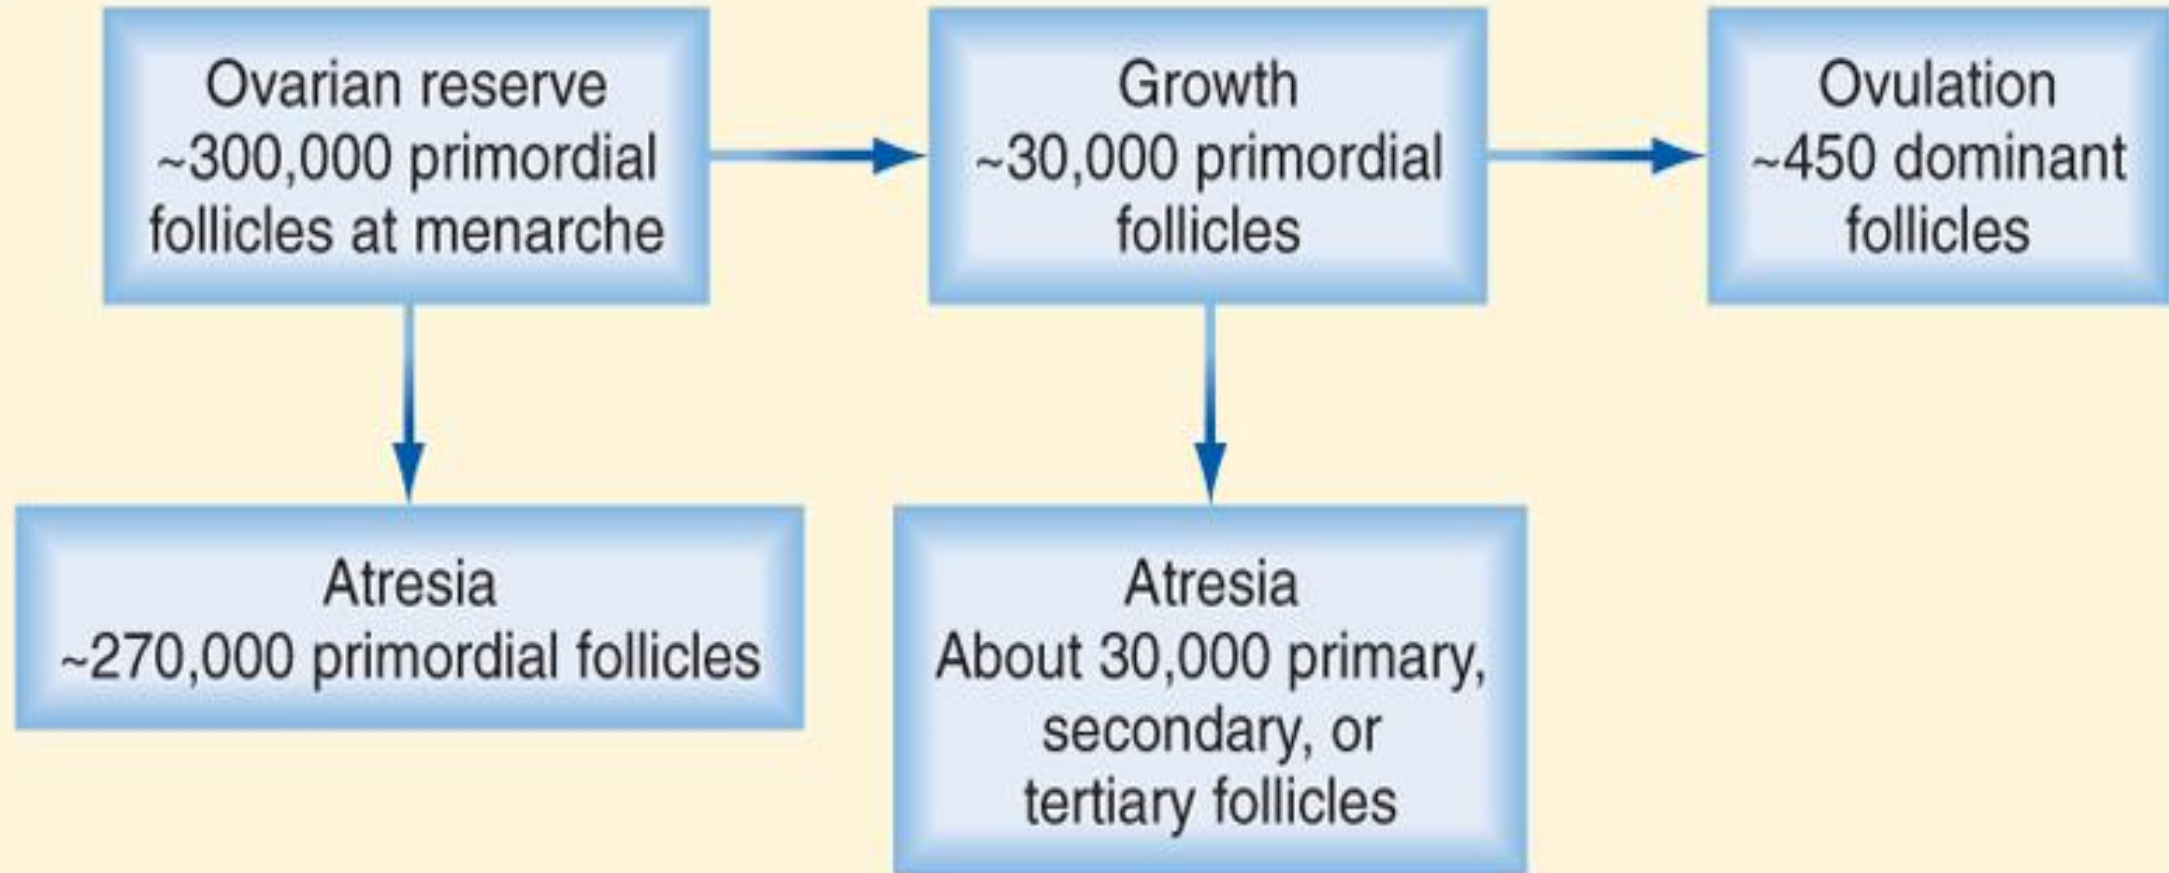

# The Follicular Phase

# Ovarian Follicles

Accelerated  
Follicular  
Growth

**Estrogen causes granulosa cells to form more FSH receptors**

**Pituitary FSH & estrogens promote LH receptors on granulosa cells → LH & FSH Stimulation and rapid ↑ in follicular Secretion**

**Estrogen from follicles and increasing LH from Pituitary cause ↑ follicular proliferation and secretion**

# Fate of Follicles

**One follicle Fully matures Each Month**

**Remaining 5-11 developing follicles involute → Atresia**

**Large amount of Estrogen act on  
hypothalamus to ↓ FSH**

**One follicle reaches a diameter of 1-1.5cm →  
Mature Follicle**

# Follicular Development

# Follicular Development

(a) Primordial follicle

(b) Late primary follicle

(d) Secondary follicle

(d) Mature (graafian) follicle

# Stages of Follicular Development

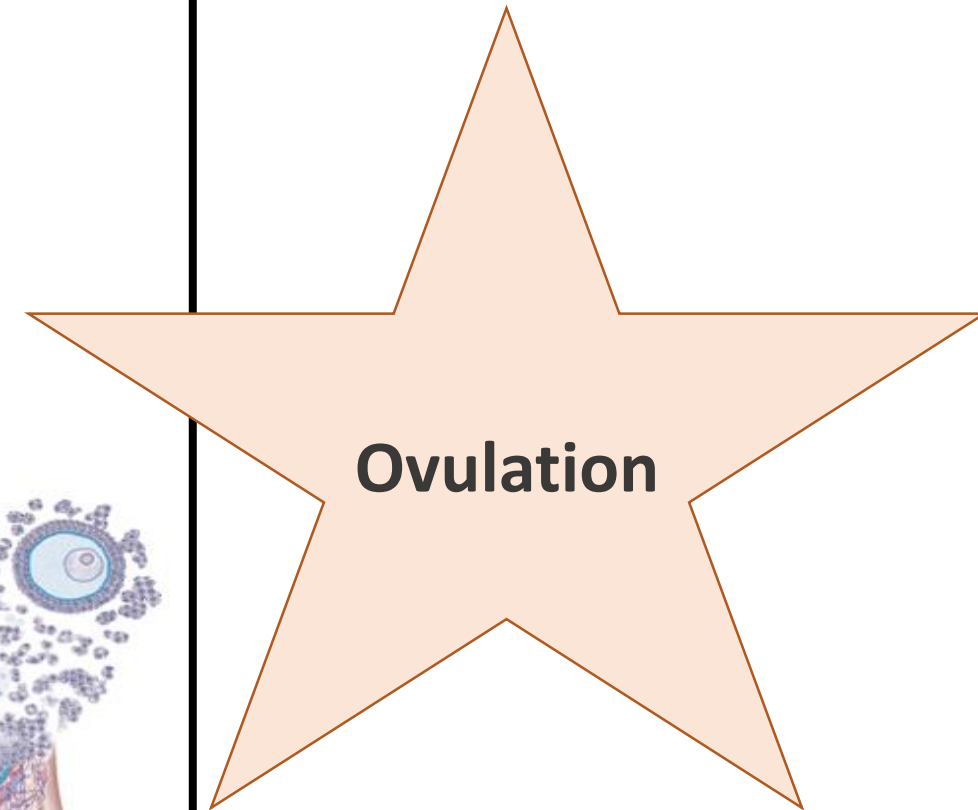

# Ovulation

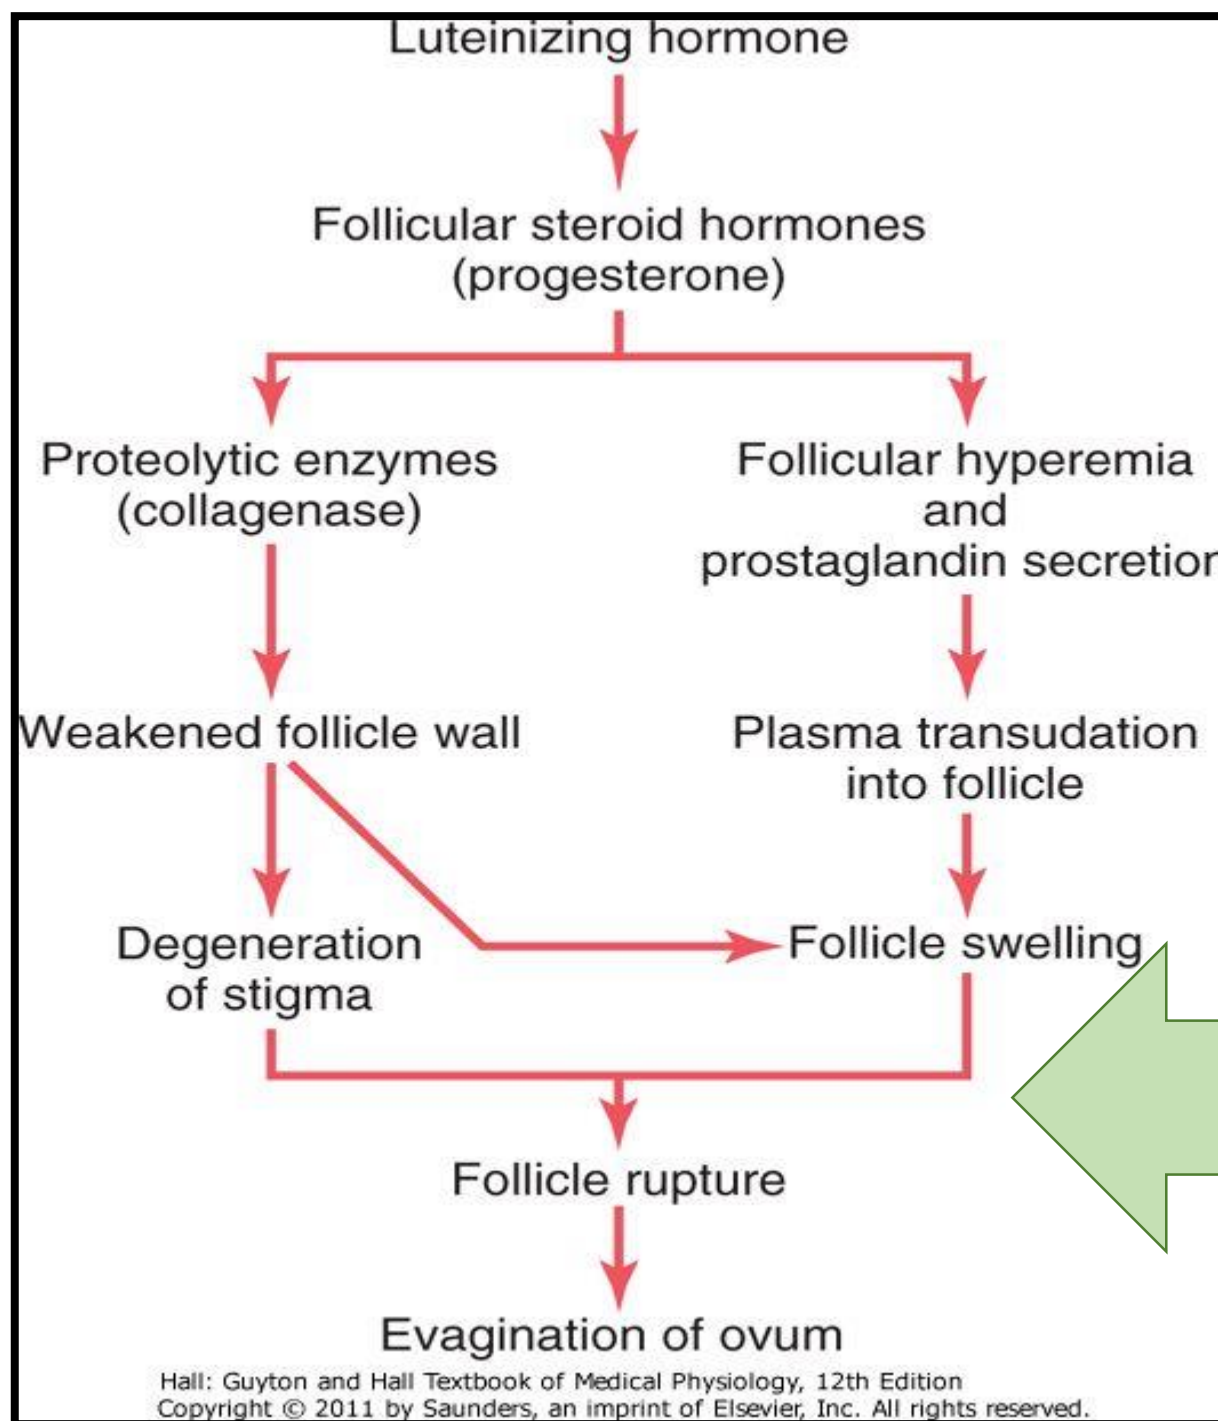

# SYMPTOMS OF OVULATION

# Rupture of the Graafian Follicle with Liberation of Ovum

# Mechanism of Ovulation

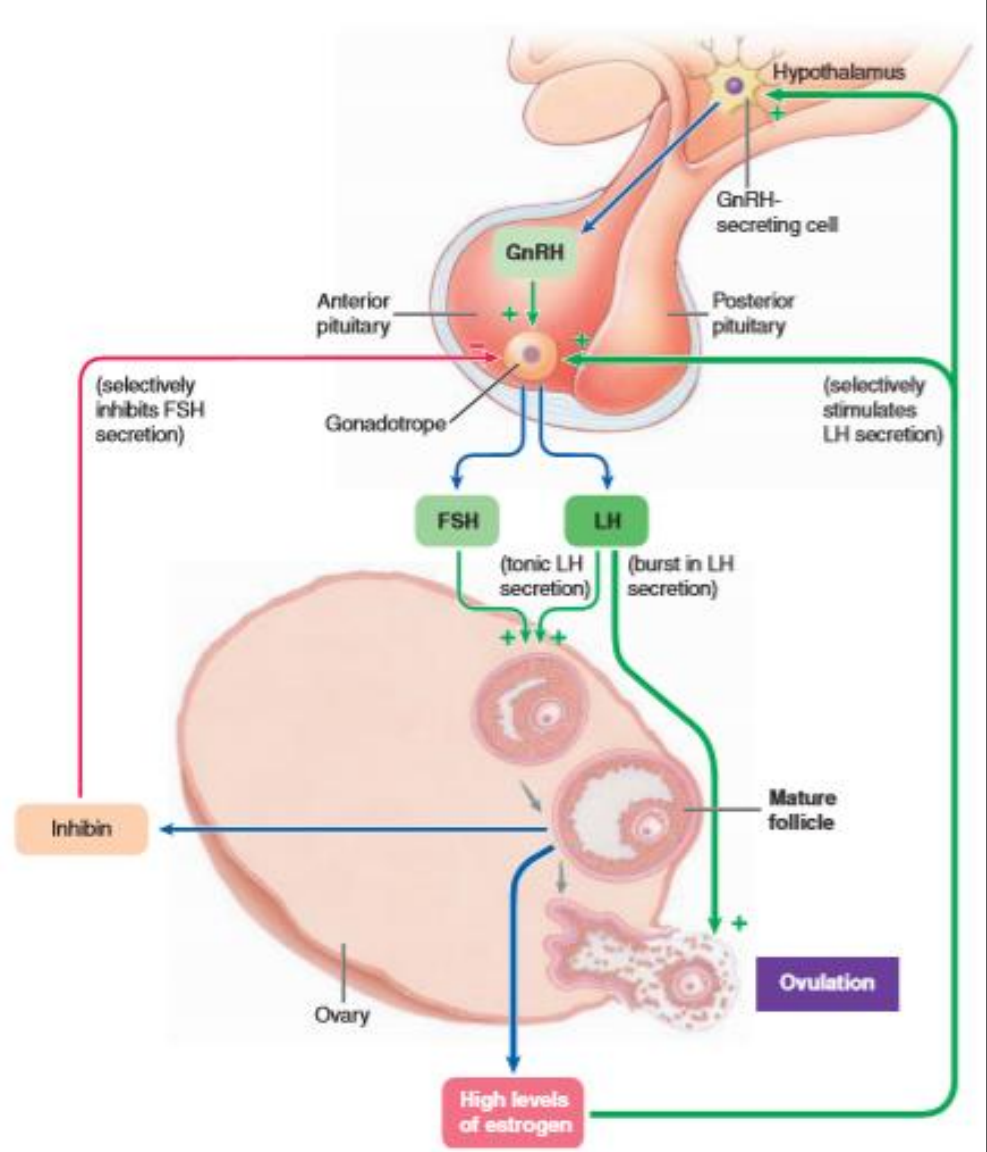

↑ Follicular Growth  
+  
↓ Estrogen  
+  
Initiation of Progesterone

● **FIGURE 20-20** Feedback control of FSH and tonic LH secretion during the follicular phase.

● **FIGURE 20-21** Control of the LH surge at ovulation.

# Mechanism of Ovulation

# Plasma Concentrations of FSH and LH

# Plasma Concentrations of Estrogens and Progesterone

# Summary of Causes of ovulation

**1- The sharp increase in LH from anterior pituitary**

**2- Local weakness and degeneration of the ovarian surface**

**3- The increased intrafollicular pressure**

**4- Muscular contraction of the ovarian wall**

# The Luteal Phase

**Yellowing**

# The Luteal Phase

## The menstrual cycle

# Fate Of Corpus Luteum

If Fertilization  
does not occur →  
Corpus Luteum →  
Corpus albicans

If Fertilization  
occurs →  
Pregnancy

# Luteal Phase of Ovarian Cycle

**Duration most constant of phases**

**Lasts for 14 days in 28 days cycle (day 15-28)**

**After ovulation, mature follicle collapses to form corpus luteum under the influence of LH**

- **Corpus luteum grows to 1.5cm after 7/8 days**
- **Secretes Progesterone, Estrogen, Relaxin and Inhibin**
- **Growth of corpus Luteum depends on Vascular Endothelial derived Growth Factor (VEGF)**

**Relaxin** relaxes the ligaments of pelvis & softens the cervix

**Inhibin** inhibits FSH secretion by anterior pituitary

# Function of Luteinizing Hormone

**Corpus luteum secretes excess of estrogen and progesterone**

**LH surge causes theca and granulosa cells luteinization and these cells undergo**

- 
- 1. Proliferation**
  - 2. Enlargement**
  - 3. Secretion**
  - 4. Degeneration**

**No Fertilization-Involution of Corpus Luteum (24<sup>th</sup> Day) → Corpus Albicans  
If Pregnancy occurs, Corpus Luteum Persists and no menses**

- **Granulosa cells** in corpus luteum produce estrogens and more progesterone
- Theca cells form mainly the androgens androstenedione and testosterone rather than female sex hormones, but they are converted by **AROMATASE** enzyme → estrogens

# The Monthly Endometrial Cycle

Cyclic changes  
in the  
Endometrium  
every 28 days

under the control  
of Ovarian  
hormones

# Uterine Cycle and Menstruation

- Cyclical changes in uterus → menstrual bleeding once during each menstrual cycle
- Lasts about 5-7 days after degeneration of corpus luteum

# Uterine Wall

Copyright © The McGraw-Hill Companies, Inc. Permission required for reproduction or display.

(a)

- Uterine Wall is composed of three layers
  - Perimetrium – outermost serous layer; the visceral peritoneum
  - Myometrium – middle layer; interlacing layers of smooth muscle
  - Endometrium – mucosal lining of the uterine cavity changes in thickness during the menstrual cycle

# The Menstrual Phase

# The Menstrual Phase

**discharge of blood  
and endometrial  
debris form vagina**

**start of a new Ovarian  
cycle coinciding with the  
end of luteal phase and  
onset of the follicular  
phase**

**First day of  
menstruation is  
considered start of a  
new cycle**

**Degeneration of corpus luteum**

```
graph TD; A[Degeneration of corpus luteum] --> B[Decreased level of estrogen and progesterone]; B --> C[Decreased Ovarian hormones stimulate Prostaglandin release]; C --> D[Prostaglandin causes Vasoconstriction of endometrial vessels → disrupting blood supply to endometrium]; D --> E[Bleeding along with the Endometrial debris from the Uterine cavity is known as Menstruation];
```

**Decreased level of estrogen and progesterone**

**Decreased Ovarian hormones stimulate Prostaglandin release**

**Prostaglandin causes Vasoconstriction of endometrial vessels → disrupting blood supply to endometrium**

**Bleeding along with the Endometrial debris from the Uterine cavity is known as Menstruation**

# The Menstrual Phase

**Involution of endometrium to 65% of thickness**

**Vasospasm of tortuous blood vessels and decreased nutrients**

**→ Necrosis in Endometrium → Menstruation  
(40 ml Blood + 35 ml Serous Fluid)**

**Blood, Desquamated endometrium, cervical mucus, vaginal cells**

Does all the Uterine lining gets sloughed off during Menstruation?

**Uterine lining mostly sloughs during each period except for a deep thin layer of epithelial cells and glands → regeneration of endometrium**

# The Menstrual phase

**Local uterine prostaglandin stimulates mild rhythmic contractions of the uterine myometrium**

**The contractions help expel the blood and endometrial debris from the uterine cavity out through the vagina as Menstrual Flow**

**↑ uterine contractions by prostaglandin overproduction → the menstrual cramps (Dysmenorrhea)**

Blood does not clot due to **Fibrinolysin** released with necrotic material

Uterine contractions are initiated by **Prostaglandins** and other substances in desquamated material

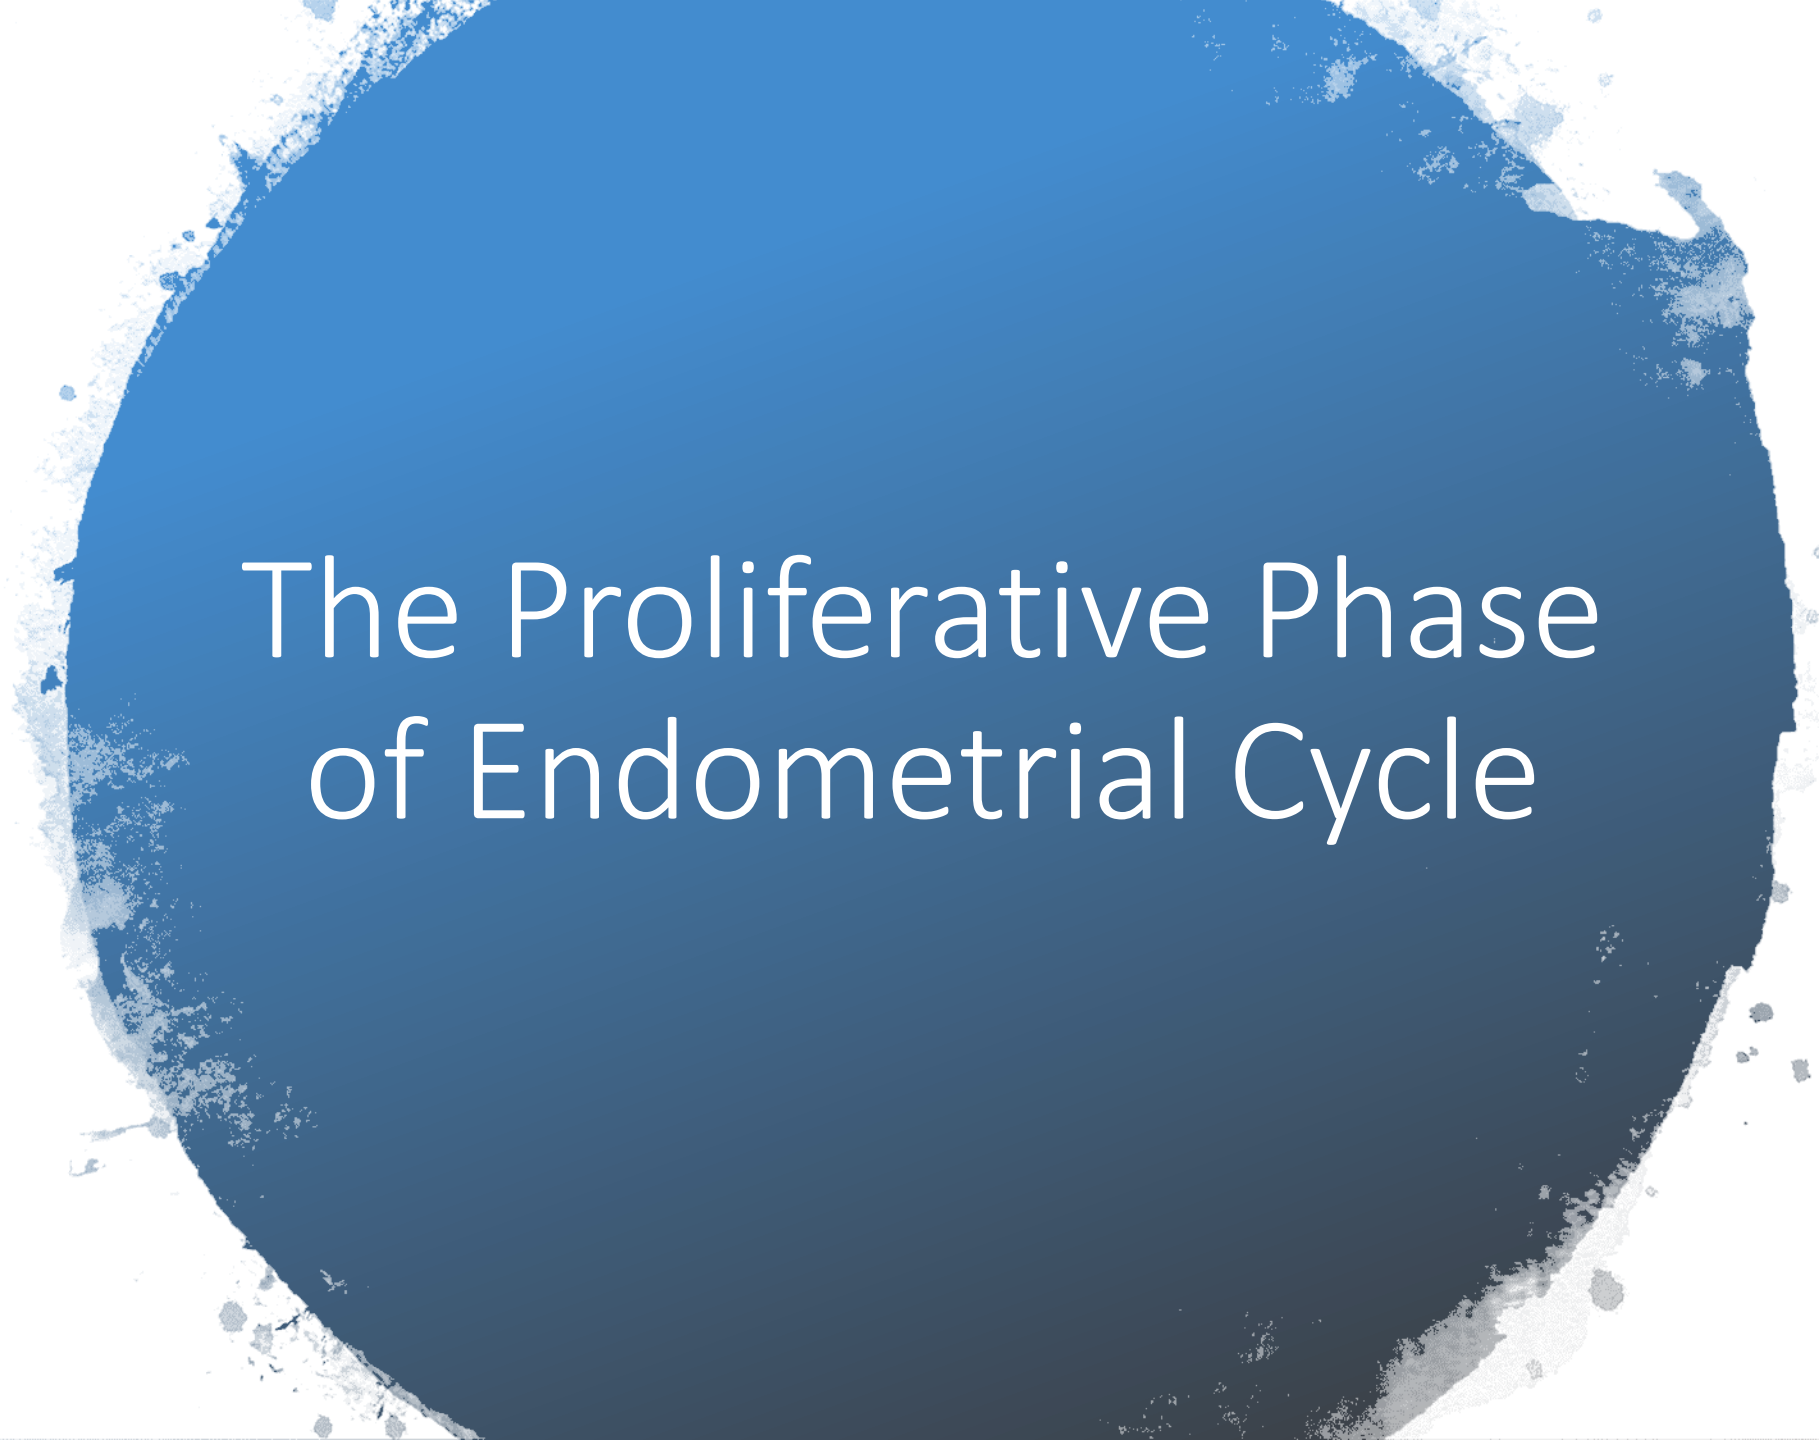

Within 4-7 days the blood loss stops due to **re-epithelialization**

# The Menstrual Phase

- Average blood loss during a cycle  
**50-150 mL**

- Menstrual blood flow

Has large number of Leukocytes – **Leukorrhea** so resistant to infection

# The Proliferative Phase of Endometrial Cycle

# The Proliferative Phase (Estrogen)

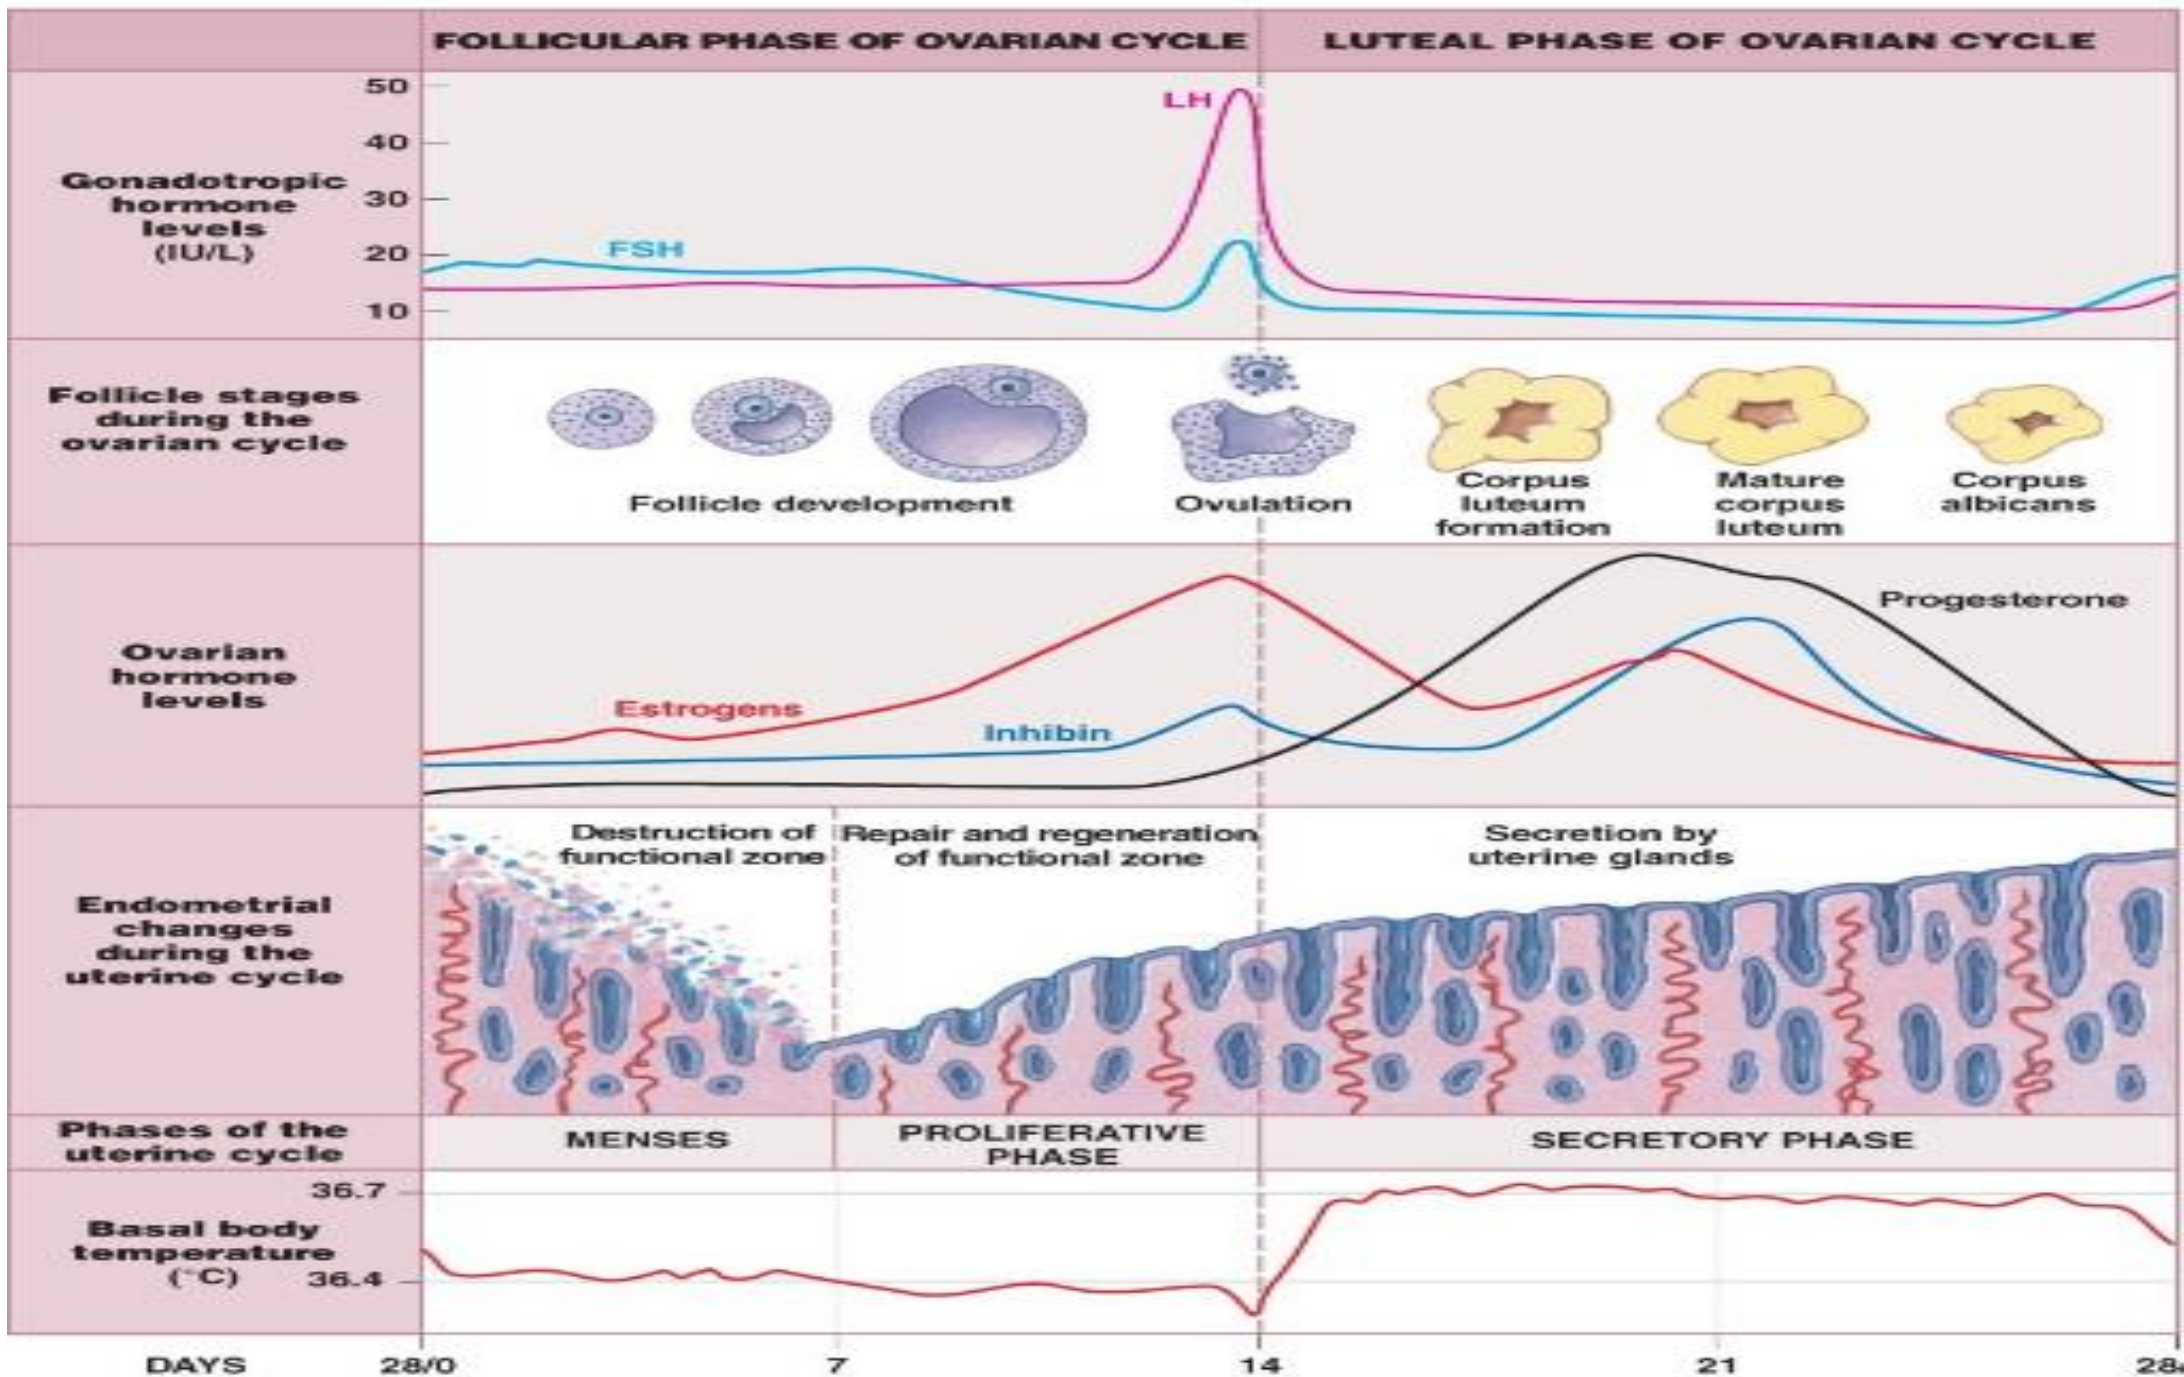

After menstruation only thin endometrium is left

Estrogens → Endometrium ↑ in thickness

Re-epithelialization in 4-7 days after start of menstruation

**By the time of ovulation endometrium is 3-5 mm thick**

**Endometrial glands especially of cervical region secrete mucus that guides sperm to enter the into uterus tortuous & rich of mucin, glycogen**

Secretory Phase/  
Progestational phase

## Secretory Phase/ Proggestational phase

Corpus luteum secretes Progesterone and Estrogens

- **Progesterone → swelling and secretory development of endometrium (glands, lipid & glycogen deposit, ↑ blood flow)**
- **Estrogens → slight cellular Proliferation in Endometrium**

**Highly Secretory Endometrium for Implantation of Fertilized Ovum**

## Secretory or Proggestational Phase

- 1 week after ovulation endometrial thickness is **5-6mm**
  - Appropriate conditions for fertilized ovum
    - **Uterine Milk** provides nutrition
- Once ovum implants it gets nutrition from rich endometrium

# Summary of Endometrial Cycle

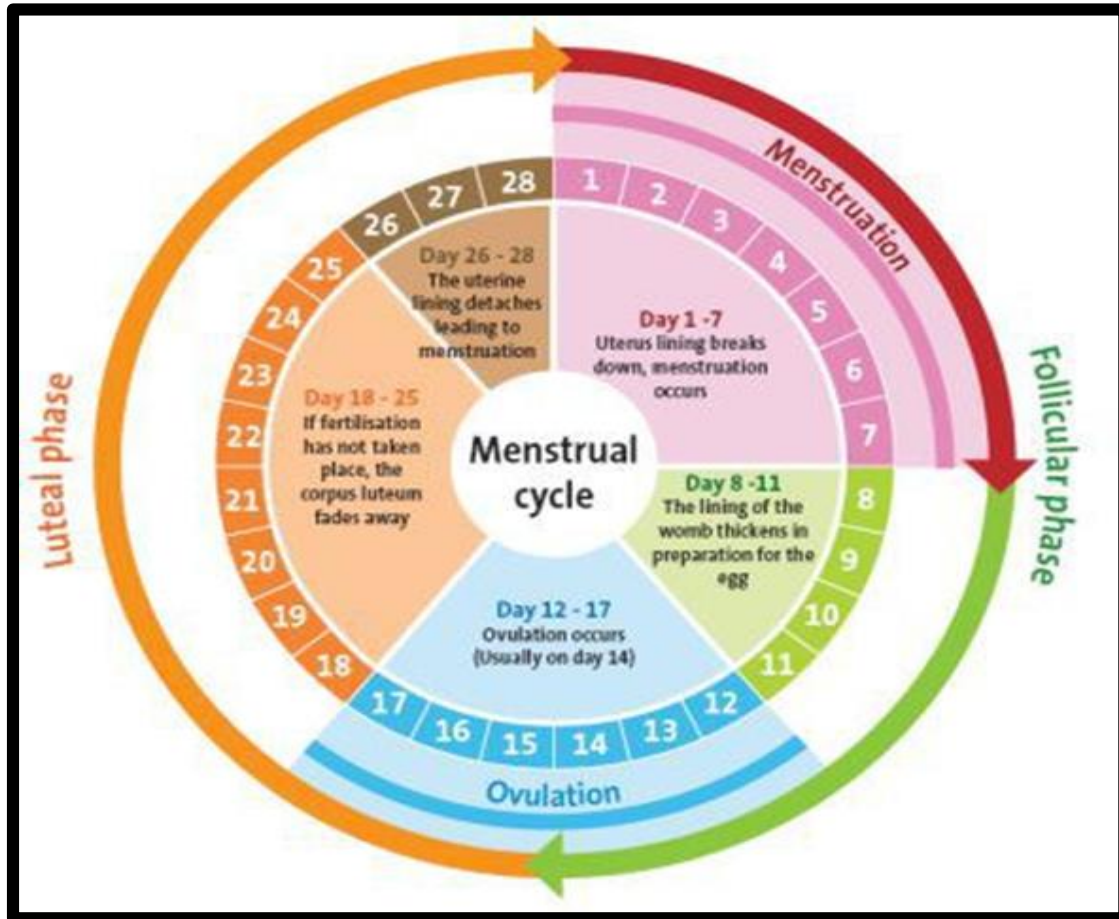

Ovarian Estrogen

14 Days

PGs

<b>Proliferative Phase</b>	<b>↑ No of Stromal Cells</b> <b>↑ Growth of Endometrial Glands</b> <b>Mucus</b> <b>Endometrial thickness is 3-5 mm at ovulation</b>
<b>Secretory Phase</b> Estrogen & Progesterone	<b>Cellular Proliferation</b> <b>Glands increase in tortuosity</b> <b>↑ Lipid &amp; Glycogen in glandular cells</b> <b>Blood flow ↑</b> <b>Endometrial thickness is 5-6 mm</b>
<b>Menstrual Phase</b>	<b>No fertilization</b> <b>Corpus Luteum involutes</b> <b>↓ Estrogen and Progesterone</b> <b>Involution of Endometrium</b> <b>Spasm of Blood vessels</b> <b>Blood + Desquamated tissue + PGs</b> <b>40 ml blood + 35ml Serous fluid</b>

# Summary

# Regulation of Female Monthly Rhythm

**Hypothalamus (Arcuate nuclei, preoptic area, anterior part)  
secretes Gonadotropin Releasing Hormone  
(Intermittent Pulsatile)**

**Intermittent Pulsatile Release of FSH & LH From Anterior Pituitary**

**Negative feedback to ↓ FSH LH by  
Estrogen in small amounts &  
Progesterone  
Inhibin (Corpus Luteum Granulosa  
Cells)**

**Positive Feedback Effect of Estrogen &  
Progesterone  
before OVULATION  
The Preovulatory LH Surge**

# Feedback Oscillation of Hypothalamic Pituitary Ovarian Axis

Feedback  
Oscillation of  
Hypothalamic  
Pituitary  
Ovarian Axis

Sequence  
of Events

**Post ovulatory secretion of Ovarian Hormones and ↓ of Pituitary Gonadotrophins**

**Follicular Growth Phase → Corpus Luteum shrinks before menstruation and estrogen, progesterone & Inhibin ↓ leading to ↑ in FSH**

**The Preovulatory Surge of FSH & LH causes Ovulation. ↑ LH Leads to Ovulation and Corpus Luteum**

# Anovulatory Cycles

- **At puberty and before menopause**
- **If the preovulatory surge of LH is not of sufficient magnitude, ovulation will not occur → Anovulatory**
- **Lack of ovulation → no corpus luteum & no progesterone in latter part of cycle**
- **Cycle is shortened but rhythm continues**

# Menstrual Pain

1

Uterus sheds the internal lining during periods

2

Prostaglandins are produced as part of body's healing process

3

Excess prostaglandins result in **abdominal cramping** and **pain in thighs**

[www.painfulperiods.in](http://www.painfulperiods.in) | A campaign against dysmenorrhea Pledge your support on    

**Periods are normal. Period pain is not.**

## DYSMENORRHEA CAUSES

### Primary Dysmenorrhea

Natural uterine contractions due to high prostaglandin concentration, aimed at shedding its lining

### Secondary Dysmenorrhea

- Endometriosis
- Uterine fibroids
- PID

**Extreme weight change**

**Breastfeeding**

**Medications**

**Pregnancy**

**Thyroid malfunction**

## **Unexpected Causes of Irregular Periods**

**Over-exercising**

**Problems with reproductive organs**

**Contraception**

**Stress**
